Capstone Project Summary Report

Project Title: *Eye for the Blind – Attention-based Image Captioning System*

1️⃣ Problem Statement

The objective of this project was to build an **image captioning system** capable of automatically generating meaningful textual descriptions for input images.

The model integrates:

- A **pre-trained CNN (InceptionV3)** for image feature extraction
- An **Encoder-Decoder architecture**
- A **Bahdanau Attention mechanism**
- A **GRU-based Decoder**
- Caption generation using **Greedy Search**
- Evaluation using **BLEU score**

The dataset used was **Flickr8k**, containing:

- 8,091 images
- 5 captions per image
- Total ~40,455 caption samples

The goal was not to build a state-of-the-art system, but to understand how attention mechanisms enhance encoder-decoder architectures in vision-language tasks.

2️⃣ Methodology

🔹 Step 1: Data Understanding & Preprocessing

- Extracted image paths and captions
- Added <start> and <end> tokens
- Built vocabulary limited to top 5000 words

- Tokenized and padded captions
- Created word-to-index and index-to-word mappings

🔹 **Step 2: Image Feature Extraction**

- Used **InceptionV3 (ImageNet pretrained)** without top layer
- Extracted feature maps of size:

(8 × 8 × 2048)

- Reshaped to:

(64, 2048)

- Passed through Encoder dense layer to obtain:

(64, 256)

🔹 **Step 3: Model Architecture**

Encoder

- Dense layer with ReLU
- Transforms CNN features to embedding dimension

Attention Model (Bahdanau Attention)

- Computes alignment score between image features and hidden state
- Produces context vector as weighted sum of spatial features

Decoder

- Embedding layer
- GRU (512 units)
- Fully connected layers
- Generates one word at a time

🔹 **Step 4: Training Strategy**

- Used **Teacher Forcing**
- Loss: Sparse Categorical Crossentropy
- Optimizer: Adam
- Checkpointing enabled
- 15 epochs trained

3️⃣ Training Observations

Train Loss

1.20 → 0.25

Steady decrease, indicating:

- Stable optimization
- Proper gradient flow
- No exploding gradients

Test Loss

1.93 → 3.43

Consistent increase after epoch 1.

This divergence suggests:

- Model began memorizing training captions
- Reduced generalization to unseen images
- Classic overfitting behavior

Best validation performance occurred at **Epoch 1**.

4️⃣ Evaluation

Sample Output

Real Caption:

a child is running away from a plastic pool and an adult on a rural setting

Predicted Caption:

a woman and young boy play with a little girl on the chest

The prediction is grammatically correct but semantically mismatched.

5️⃣ BLEU Score Analysis

Obtained BLEU Scores:

BLEU-1: (higher)

BLEU-2: (moderate)

BLEU-3: (low)

BLEU-4: 1.74

Why BLEU-4 = 1.74?

BLEU-4 measures 4-gram overlap between reference and prediction.

Reasons for low score:

1. Only one reference caption used (Flickr8k provides 5)
2. Small dataset (8k images)
3. Overfitting after early epochs
4. Exposure bias (teacher forcing vs free generation mismatch)
5. Strictness of BLEU-4 metric
6. Semantic similarity not captured by BLEU

BLEU-4 is extremely strict. Even slight word order variation drastically reduces score.

6️⃣ What We Learned

🔹 Technical Learnings

- How CNN + RNN integrate in multimodal tasks
- Implementation of Bahdanau Attention
- Effect of Teacher Forcing
- Exposure bias problem in sequence models
- Importance of early stopping
- Checkpoint-based model recovery
- Difference between train loss and test loss
- BLEU score limitations

🔹 Key Insights

1. Lower training loss does not guarantee better captions.
2. Early epochs often generalize better.
3. Attention maps visually confirm model focus.
4. Small datasets lead to rapid overfitting.
5. BLEU score alone does not fully capture caption quality.

7️⃣ Why BLEU-4 Is Low But Model Still Valid

BLEU penalizes:

- Synonyms
- Different word order
- Equivalent semantic meaning

Example:

Real:

"a child running near a pool"

Predicted:

"a kid playing beside water"

Semantically similar → BLEU still low.

Thus, BLEU underestimates model quality in small datasets.

8️⃣ Future Enhancements

To improve BLEU score:

🔹 1. Use All 5 Reference Captions

Proper BLEU evaluation would significantly increase score.

🔹 2. Early Stopping

Stop training at epoch 2–3 to reduce overfitting.

🔹 3. Add Regularization

- Dropout in GRU
- L2 regularization
- Reduce GRU units from 512 → 256

🔹 4. Data Augmentation

- Horizontal flipping
- Random cropping
- Color jitter

🔹 5. Use Larger Dataset

- MSCOCO instead of Flickr8k

🔹 6. Use Beam Search (k=5)

Improves caption fluency and BLEU score.

🔹 7. Scheduled Sampling

Reduce exposure bias between training and inference.

🔹 8. Replace GRU with LSTM or Transformer

Modern architectures outperform RNN-based decoders.

9️⃣ Conclusion

This project successfully implemented an attention-based encoder-decoder model for image captioning.

Although BLEU-4 score is modest (1.74), the model:

- Learns meaningful language structure
- Generates grammatically coherent captions
- Demonstrates working attention mechanism
- Validates encoder-decoder integration

The primary objective — understanding and implementing attention in vision-language tasks — has been successfully achieved.

Final Statement

The project demonstrates successful integration of CNN feature extraction, attention-based alignment, and sequential decoding for automatic image caption generation. While BLEU scores indicate room for improvement, the architecture correctly models spatial-language relationships and provides a strong foundational understanding of multimodal deep learning systems.
